THIRD SYMPOSIUM ON THE HISTORY OF AEROSOL SCIENCE

Organizer: David S. Ensor

This pre-conference symposium will bring together researchers who will discuss the evolution of the field of aerosol science and engineering. Presenters will provide a historical perspective of the field and describe the work of giants, evolution of the scientific concepts and instruments. Much of what we do today has a connection to the past – so come take a peek and we can leap into the future.

6:30 pm – 10:00 pm

Join your friends and colleagues on Wednesday evening, September 13, 2006, for an evening dinner cruise aboard the Anson and Betsey Northrup vessels of the Padelford Packet Boat Co.

Founded in 1969, the Padelford Packet Boat Co. is Minnesota's oldest and largest riverboat company. The Padelford fleet of four large riverboats has welcomed more than 3 million passengers on board to cruise the Mississippi from its landings in Minneapolis and St. Paul.

The IAC private charter cruise will leave from the Harriett Island landing in St. Paul. Transportation will be provided from the Crowne Plaza St. Paul Riverfront to the landing. Vessel boarding will commence at 6:30 pm, and departure will be at 7:00 pm. The return to Harriett Island is scheduled for 10:00 pm. Buses will transport you back to the Crowne Plaza St. Paul Riverfront.

INTERNATIONAL DINNER

25TH ANNIVERSARY OF AAAR: CELEBRATION LECTURE

Sheldon K. Friedlander

This exciting talk will describe how aerosol science and engineering is an “enabling discipline” and describe the various areas where aerosol scientists have made contributions. Starting with an historical perspective, the talk will provide the exciting opportunities for aerosol scientists in the future.

The talk will be followed by recognition of the activities of the AAAR in the last 25 years. The contribution of international societies and the growth of the International Aerosol Research Assembly (IARA) will also be recognized.

AMERICANS WITH DISABILITIES ACT

The IAC will use its best efforts to provide reasonable accommodations for attendees with disabilities.

CM POINTS

The American Board of Industrial Hygiene will award CM points to CIHs as follows:

.5 points per half day, 4.5 Industrial Hygiene CM points – approval #: 06-070

All participants of the 2006 IAC are encouraged to contact their respective professional certifying agency for the applicability of the IAC Conference program toward additional CM points and CEU credits.

AWARD PRESENTATIONS

Awards will be presented immediately after each plenary session. Please refer to the Schedule-at-a-Glance for the specific award presentation times. Join us in honoring the recipients of AAAR's major awards: Thomas T. Mercer, Kenneth T. Whitby Award, David Sinclair Award, Sheldon K. Friedlander Award, and Benjamin Y.H. Liu Award. The IARA awards include: Fissan-Pui-TSI Award, Fuchs Memorial Award, and International Aerosol Fellow Award. The GAeF will also present the Smoluchowski Award.

SPEAKER READY ROOM

There will be a Speaker Ready Room for presenters in the Judges' Suite at the Crowne Plaza St. Paul Riverfront. It is required that all speakers visit the Speaker Ready Room the day prior to their presentation. There will be a technician in the room to assist speakers with their presentation preparation. TUTORIALS

Sunday, September 10

Session One: 8:00 am – 9:40 am

1. Introduction to Aerosol Mechanics I

Dr. William C. Hinds, UCLA, School of Public Health, Center for Occupational and Environmental Health, Department of Environmental Health Science, Los Angeles, CA

These two courses form a sequence that covers basic aerosol mechanics (particle motion) at an introductory level. Topics include: Stokes law, settling velocity, slip correction, aerodynamic diameter, non-spherical particles, acceleration, relaxation time, stopping distance, impaction, isokinetic sampling, diffusion, and coagulation. The course covers theory and applications and is suitable for those new to the field and for others who want to brush up on the basics.

William Hinds is a professor of environmental health sciences at the UCLA School of Public Health. He received a bachelor's degree in mechanical engineering from Cornell University and a doctorate in environmental health from Harvard University.

2. Aerosol Thermodynamics

Dr. Athanasios Nenes, Georgia Institute of Technology, Schools of Earth and Atmospheric Sciences and Chemical and Biomolecular Engineering, Atlanta, GA

The past few years have seen a significant and growing interest in measuring the potential of aerosols to act as cloud condensation nuclei (CCN). Numerous techniques during the years have been developed for this purpose; they all involve exposing of an aerosol sample to a controlled water vapor supersaturation and optically detect the size and concentration of droplets that form. We will review the diverse set of designs and detection approaches, as well as theoretically analyze the methodology embodied by each CCN instrument. Results from laboratory and field experiments will be presented to demonstrate the capabilities of these instruments and highlight their importance for quantitative understanding of aerosol-cloud interactions.

Athanasios Nenes is an assistant professor in the Schools of Earth and Atmospheric Sciences and Chemical and Biomolecular Engineering at the Georgia Institute of Technology. He received a diploma in chemical engineering from the National Technical University of Athens, a master's degree in atmospheric chemistry from the University of Miami, and a doctorate in chemical engineering from the California Institute of Technology.

3. Air Pollution Exposure Assessment: Implications for Particulate Matter Epidemiology

Dr. Jeremy A. Sarnat, Department of Environmental and Occupational Health, Rollins School of Public Health of Emory University, Atlanta, GA

Most epidemiologic studies examining the health effects from exposure to ambient particulate matter have used measurements from central site monitors as surrogates of corresponding personal exposures. The validity of this practice and its potential for introducing exposure misclassification bias into the observed epidemiologic results has been widely debated. In 1998 the National Research Council recommended that further research be conducted to characterize personal exposures to PM_{2.5}, including its relationship to ambient PM_{2.5} and other multi-pollutant exposures. To address these issues, several panel studies were designed and conducted that characterized actual multi-pollutant personal exposures throughout the United States and Europe. This tutorial reviews the major results from these exposure studies and summarizes the collective findings for their impact on interpreting particulate matter epidemiologic studies. Directions for future exposure assessment and epidemiology research, including characterizing personal exposures to chemically- and size-resolved PM_{2.5}, will also be discussed.

Jeremy Sarnat is an assistant professor at the Rollins School of Public Health of Emory University specializing in characterizing personal exposure to criteria air pollutants. He received his master's degree in environmental risk assessment and doctorate in environmental exposure assessment from Harvard University.

4. Aerosol Characterization using Plasma Spectrochemistry

Dr. Martin M. Shafer, Environmental Chemistry and Technology Program, University of Wisconsin-Madison, Madison, WI

Detailed elemental and chemical speciation analysis of aerosol particulate matter (PM) can provide valuable information on PM sources, transformations, and climate forcing. Certain PM sources may best be resolved using trace metal signatures, and elemental fingerprints can supplement and enhance molecular marker analysis of PM for source apportionment modeling. In the search for toxicologically relevant components of PM, health studies are increasingly demanding more comprehensive characterization schemes.

It is also clear that total metal analysis is at best a poor surrogate for the bioavailable component, and analytical techniques that address the labile component or specific chemical species are needed.

However, traditional analytical techniques (XRF, PIXIE, INAA) that have been widely applied in the past to determine the elemental composition of PM do not have the required sensitivity and

accuracy to quantify the full suite of trace elements in the microgram masses of samples typical of many fine particle collections. This state of affairs is exacerbated by the current trend toward even smaller sample sizes that is being driven by (1) particle size-resolved sampling; (2) personal sampler collections; and (3) fine temporal scale (1-4 hr) sampling.

Inductively-Coupled Plasma Mass Spectrometry (ICP-MS) is emerging as a powerful tool for the determination of the elemental composition and chemical speciation of atmospheric aerosols. In addition to exhibiting extreme sensitivity and high signal to noise, the technique offers other unique capabilities including: high precision, extremely wide dynamic range, a large element menu, and elemental isotopic capability. These features significantly advance the state-of-the art (making it the method of choice for most applications) over traditional aerosol analysis techniques. However, full realization of these advantages is contingent upon several key factors as prerequisites:

1. Full integration of clean techniques into collection/processing/analysis methods;
2. Application of efficient, unbiased, and precise solubilization methods; and
3. Minimization of polyatomic interferences in the ICP-MS analysis.

This tutorial will address each of these three areas in detail, providing practical solutions and recommendations for a variety of real-world applications. It will be stressed that ultra-trace ICP-MS analysis cannot be performed in isolation, but must be part of a complete package of contamination and interference control. The importance and practical implementation of method blanks and use of standard reference materials in protocol validation will be covered. Metrics of ICP-MS performance will be compared with those from more traditional methods as specifically relates to ambient aerosol characterization.

Contamination control strategies for specific steps (substrate preparation, field sampling, post-collection processing, and ICP-MS analysis) of the overall method will be discussed. Lack of suitable solubilization methods for the complete suite of elements comprising atmospheric particulate matter has been a barrier to the use of solution nebulization techniques, including ICP-MS, for the analysis of aerosols. Concerns have included extraction efficiency, volatilization losses, contamination, and issues of dilution and sensitivity. This short course will detail digestion protocols that our research group (and others) has developed to effectively address these issues. Microwave-based methods will be emphasized. Various “selective” dissolution approaches for aerosols will also be covered – focusing on methods that target the labile metals/components. A host of interference control approaches for ICP-MS analysis will be discussed, including: (1) the use of high efficiency desolvating nebulizers; (2) collision/reaction cell ICP-MS; and (3) high mass resolution ICP-MS.

The tutorial will conclude with a discussion of several advanced applications of ICP-MS in the context of aerosol characterization. These will include chemical speciation analysis (oxidation state speciation, HPLC-ICP-MS), high precision isotope ratio analysis and applications, and direct solids/particle analysis using laser-ablation-ICP-MS.

Session Two: 10:00 am – 11:40 am

5. Introduction to Aerosol Mechanics II

Dr. William C. Hinds, UCLA, School of Public Health, Center for Occupational and Environmental Health, Department of Environmental Health Science, Los Angeles, CA

These two courses form a sequence that covers basic aerosol mechanics (particle motion) at an introductory level. Topics include: Stokes law, settling velocity, slip correction, aerodynamic diameter, non-spherical particles, acceleration, relaxation time, stopping distance, impaction, isokinetic sampling, diffusion, and coagulation. The course covers theory and applications and is suitable for those new to the field and for others who want to brush up on the basics.

William Hinds is a professor of environmental health sciences at the UCLA School of Public Health. He received a bachelor's degree in mechanical engineering from Cornell University and a doctorate in environmental health from Harvard University.

6. Atmospheric Nucleation

Dr. Markku Kulmala, University of Helsinki, Department of Physical Sciences, Helsinki, Finland

In order to be able to better understand the health and climatic effects of atmospheric aerosols, the formation and growth processes of atmospheric aerosols should also be better understood. Nucleation, the formation of ultrafine particles detected at a few nm, and subsequent growth to ~100 nm in 1-2 days, has been observed frequently all around the world, particularly in the continental boundary layer. Such observations span from Arctic and Antarctic areas, over the remote boreal forest, and urban and suburban areas in Scandinavia, to industrialized agricultural regions in Europe and North America, to coastal environments around Europe, and to Asian and American megacities. Our recent overview summarized the formation and growth properties from a global point of view, quantifying especially the formation and growth rates of nucleation events where available. It has been proposed and also observed that atmospheric new particle formation depends on the sulfuric acid concentration. On the other hand some observations support the idea that atmospheric ions are participating in new particle formation. In this tutorial, different atmospheric nucleation mechanisms – including barrierless (kinetic), binary, ternary, and ion induced nucleation as well as recently proposed cluster activa-

tion mechanisms – are explained and compared with atmospheric observations and laboratory experiments.

Markku Kulmala is an academy professor and professor in physics at the University of Helsinki, Finland. He acts also as a director of the Division of Atmospheric Sciences in the Department of Physical Sciences in Helsinki. He received master's and doctorate degrees in physics from the University of Helsinki.

7. Human Aerosol Exposure: Toward a Mechanistic Understanding

Dr. William W. Nazaroff, Department of Civil and Environmental Engineering, University of California, Berkeley, CA

This tutorial explores the relationships between particle sources and human inhalation exposure. The tools and techniques are those of the physical sciences and engineering, stressing causal connections. The lecture draws on key chemical and physical knowledge from atmospheric aerosol science. Focusing on human exposure as the outcome of concern leads to an emphasis on the proximity between sources and receptors. Most exposure occurs while people are in enclosed spaces, so issues that influence indoor aerosols enter strongly into this lecture.

William Nazaroff is a professor of environmental engineering and chair of the energy and resources group at UC Berkeley. His research group studies indoor air pollutant chemistry and physics. They also develop and apply methods for assessing human exposure to air pollutants from major exposure sources, such as motor vehicles, power plants, and cigarettes. Dr. Nazaroff earned a doctorate in environmental engineering science at Caltech (1989).

8. Basics of Light Absorbing Carbon

Dr. Tami C. Bond, Department of Civil and Environmental Engineering, University of Illinois at Urbana-Champaign, IL

Although carbon particles contain thousands of compounds, one type of carbon is routinely separated in modeling and analysis: the kind that appears black because it absorbs light strongly. What makes this compound so special? This tutorial will briefly discuss flame formation and important sources of light-absorbing carbon. Carbon that absorbs light weakly will also be covered. I will review factors that affect absorption and scattering by these particles, including changes that occur during the time between emission and removal. This discussion leads to an overview of the role of black particles in the Earth's radiative balance. Finally, I will review common measurement methods, with particular emphasis on how light absorption can aid in or confound interpretation.

Tami Bond earned bachelor's and master's degrees in the combustion side of mechanical engineering before her interdisciplinary doctorate from the University of Washington (atmospheric sciences, mechanical engineering and civil engineering). She was a NOAA Climate and Global Change Post-doctoral Fellow and is now an assistant professor at the University of Illinois. Most of her research involves measuring and estimating emissions for climate applications.

Session Three: 1:00 pm – 2:40 pm

9. Aerosol Sampling and Transport

Dr. John E. Brockmann, Principal Member, Technical Staff,
Sandia National Laboratories, Albuquerque, NM

It is desirable that the sampled aerosol be representative of the aerosol in its original environment. Sampling and transport can alter the ambient aerosol distribution. This tutorial will provide the tools to evaluate aerosol sampling and transport systems. The mechanisms that enrich or deplete particle concentration will be identified and discussed, and correlations from the literature will be given.

Dr. Brockmann received his doctorate in mechanical engineering from the University of Minnesota in 1981 and works at Sandia National Laboratories. His areas of research include nuclear aerosols, microcontamination, particle sampling and transport, and instrumentation.

10. Measurements of Aerosol Radiative Properties

Dr. John A. Ogren, Physical Scientist, NOAA Earth System
Research Laboratory, Boulder, CO

This tutorial will cover the methods used for measurement of aerosol radiative properties, with an emphasis on in-situ measurements of aerosol light scattering, absorption, and extinction coefficients. Approaches for determining the dependence of these properties on particle size, wavelength, and relative humidity will be described, along with an overview of the results from their application in NOAA's long-term aerosol monitoring program.

Dr. Ogren received his doctorate in 1983 from the University of Washington. He leads NOAA's long-term aerosol monitoring program, which emphasizes the radiative properties of aerosols.

11. Biokinetics and Toxicology of Nanoparticles

Dr. Günter Oberdörster, University of Rochester, Rochester, NY

The rapidly developing field of nanotechnology holds many promises and benefits for developments in structural engineering, electronics, optics, consumer products, alternative energies, soil and water remediation, and nanomedicine. However, engi-

neered nanoparticles (NP, <100 nm) are also likely to result in human exposure through inhalation, ingestion, skin uptake, and injection of engineered nanomaterials. Information about safety and potential hazards is urgently needed. The new field of nanotoxicology, which can be defined as safety evaluation of engineered nanostructures and nanodevices, addresses this need by identifying NP-cell interactions through specific in vivo and in vitro tests. When inhaled, certain sizes of NP are efficiently deposited by diffusional mechanisms in all regions of the respiratory tract. The small particle size facilitates uptake into cells, transcytosis across epithelial and endothelial cells into the blood and lymph circulation to reach potentially sensitive target sites such as bone marrow, lymph nodes, the spleen, and the heart. Access to the central nervous system and ganglia via translocation along axons and dendrites of neurons has also been observed. NP penetrating the skin distribute via uptake into lymphatic channels. Endocytosis, and biokinetics are largely dependent on NP surface chemistry (coating) and in vivo surface modifications. The greater surface area per mass compared to larger-sized particles of the same chemical structure renders NP more active biologically. This activity includes a potential for inflammatory and pro-oxidant, but also anti-oxidant, activity. Evidence of mitochondrial distribution and oxidative stress response following NP endocytosis points to a need for basic research about their interactions with subcellular structures. Considerations for assessing safety of engineered NP include careful selections of appropriate and relevant doses/concentrations, the likelihood of increased effects in a compromised organism, and the development of new specific tests. This should be balanced with the benefits of possible desirable effects in medical and other applications. An interdisciplinary team approach (e.g., toxicology, materials science, medicine, molecular biology, and bioinformatics, to name a few) is mandatory for nanotoxicology research to arrive at an appropriate risk assessment.

Dr. Günter Oberdörster is a professor of toxicology at the University of Rochester, Department of Environmental Medicine. He received a DVM in veterinary medicine and doctorate in pharmacology from the University of Giessen, Germany.

12. Secondary Aerosol Formation

Dr. Paul J. Ziemann, Air Pollution Research Center and Department of Environmental Sciences, University of California, Riverside, CA

Secondary aerosol is an important component of atmospheric fine particles that generally consists of organics, sulfates, and nitrates. The processes that lead to the formation of this material are often complex, and can involve gas- and particle-phase chemistry, nucleation, and gas-particle partitioning. In this course, I will discuss the major chemical reactions and partitioning processes involved in the formation of secondary organ-

ic and inorganic aerosol (with a strong emphasis on organic aerosol) using examples from laboratory and field studies. Paul Ziemann is an associate professor of atmospheric chemistry at the University of California, Riverside. He received a doctorate in chemistry from Penn State University and was a post-doctoral researcher in the Particle Technology Laboratory at the University of Minnesota.

Session Four: 3:00 pm – 4:40 pm

13. Preparation of Nanoparticles and Nanostructured Powders by Spray Method for Their Applications in Nanotechnology

Dr. Kikuo Okuyama, Department of Chemical Engineering, Graduate School of Engineering, Hiroshima University, Higashi-Hiroshima, Japan

Recently, nanoparticles and nanostructured powders are attracting great interest in science and engineering as functional materials for use in electronics, biotechnology, etc. Spray methods are promising routes to produce single and multicomponent nanoparticles and nanostructured powders. In this tutorial, I would like to talk about: 1) General scope of particle preparation by spray pyrolysis and spray drying methods; 2) Preparation of nanoparticles using physical and chemical methods (electrospray pyrolysis, low-pressure expansion method, etc.); 3) Dispersing technology for agglomerated nanoparticles; 4) Preparation of ordered porous powders as well as particles composite by spray drying method; and 5) The application of nanoparticles and nanostructured powders in nanotechnology.

Professor Kikuo Okuyama is a professor in the Department of Chemical Engineering, Graduate School of Engineering at Hiroshima University. He received his bachelor's (1971) and master's (1973) degrees in chemical engineering from Kanazawa University, and he received his doctor of engineering (1978) in chemical engineering at the University of Osaka Prefecture. He is the president of the Japan Association of Aerosol Science and Technology (JAAS), and serves as editor of the Journal of the Society of Powder Technology Japan, Journal of Nanoparticle Research, and Aerosol Science and Technology.

14. Aerosol Technology for Drug Delivery

Dr. Warren Finlay, University of Alberta, Department of Mechanical Engineering, Edmonton, Alberta, Canada

The number of technologies under development for delivering therapeutic aerosols to the respiratory tract has increased dramatically in recent years, yielding a surprisingly large array of aerosol delivery devices and formulations. However, the fundamental principles governing these systems are relatively few, and understanding these principles allows the scientist or engi-

neer to much more easily understand the many competing pharmaceutical aerosol delivery systems. The focus of this tutorial is thus on the underlying mechanics of inhaled pharmaceutical aerosol delivery devices, including existing aqueous systems, dry powder inhalers, propellant driven metered dose inhalers, as well as new systems under development.

Warren Finlay is a professor of mechanical engineering at the University of Alberta where he holds the distinguished title of Killam Annual Professor. He received bachelor's and master's degrees in electrical engineering from the University of Alberta, and a doctorate degree in mechanical engineering from Stanford University. He is the author of the book *Mechanics of Inhaled Pharmaceutical Aerosols*, Academic Press, 2001.

15. Instrumentation and Theory of Cloud Condensation Nuclei Measurements

Dr. Athanasios Nenes, Georgia Institute of Technology, Schools of Earth and Atmospheric Sciences and Chemical and Biomolecular Engineering, Atlanta, GA

The past few years have seen a significant and growing interest in measuring the potential of aerosols to act as cloud condensation nuclei (CCN). Numerous techniques during the years have been developed for this purpose; they all involve exposing of an aerosol sample to a controlled water vapor supersaturation and optically detect the size and concentration of droplets that form. He received a diploma in chemical engineering from the National Technical University of Athens, a master's degree in atmospheric chemistry from the University of Miami, and a doctorate in chemical engineering from the California Institute of Technology.

16. Making Use of Satellite-Derived Aerosol Amounts, Distributions, and Properties

Dr. Ralph Kahn, Jet Propulsion Laboratory, Caltech, Pasadena, CA

Space-borne instruments are providing increasing amounts of data relating to global aerosol spectral optical depth, horizontal and vertical distribution, and micro-physical properties. The data sets, and many of the underlying techniques, are new. They represent a vast amount of information, potentially useful to the AAAR community. However, there are also issues, some quite

subtle, that scientific users must take into consideration. This tutorial will provide one view of the answers to the following four questions: 1.) What satellite-derived aerosol products are available?; 2.) What are their strengths and limitations?; 3.) How are they being used now?; and 4.) How might they be used in conjunction with each other, with sub-orbital measurements, and with models to address cutting-edge aerosol questions?

Ralph Kahn is a principal scientist in the Earth and Space Sciences Division at JPL. He is the aerosol scientist for the Multi-angle Imaging SpectroRadiometer (MISR) instrument, which flies aboard the NASA Earth Observing System's Terra satellite. Kahn received his doctorate in applied physics from Harvard University.

Assembling Materials and Devices from Nanoscale Building Blocks

Richard W. Siegel

The past decade has seen an explosive growth worldwide in the physical, chemical, and biological synthesis and study of a wide range of nanoscale building blocks with unique properties. The aerosol research community has made significant contributions to this growth. Great strides are now being made worldwide in our ability to assemble these nanoscale building blocks to create advanced materials and devices with novel properties and functionalities. The novel properties of nanostructures are derived from their confined sizes and their very large surface-to-volume ratios. The former give rise to unique size-dependent properties in the nanoscale (1-100 nm) regime, while the latter gives rise to the ability of nanoscale additions to conventional material matrices to dramatically change the host material's properties. A perspective of this important research area will be presented based upon specific examples from our work in the Center for Directed Assembly of Nanostructures supported by the Nanoscale Science and Engineering Initiative of the National Science Foundation. Examples will be given of directed assembly of nanoparticles, nanotubes, and hybrid structures containing these and biomolecules, to make new materials and devices that possess enhanced mechanical, electrical, optical, and bioactive properties, and multifunctional combinations thereof. The opportunities and challenges facing the worldwide research community in moving forward in this area will be considered.

Biography: Richard W. Siegel is the Robert W. Hunt Professor of Materials Science and Engineering and founding director of the Nanotechnology Center at Rensselaer Polytechnic Institute. He is also founding director of the National Science Foundation

**Indoor Aerosols: Do We Need More Data or More Science?
Lidia Morawska**

To state that indoor aerosol is different from outdoor aerosol is not a discovery. With the many sources specific to indoor environment and the myriad of factors, as well as physical and chemical processes affecting this environment, the differences are unavoidable. Yet, at times there is very little difference between the characteristics of indoor and outdoor particles: for example for naturally ventilated buildings penetration of particles of all sizes with significance to human health is almost 100 percent. To develop a complete quantitative understanding of particles in indoor environment, consideration needs to be given to the emissions from indoor sources and penetration of particles from outdoor; the type and operation of the ventilation and filtration system; building characteristics and its operation; and last but not least complex particle dynamic and physico chemistry of the processes occurring indoors.

While outdoor aerosols have been studied for decades, scientific interest in indoor aerosols followed much later and in consequence, there is still less data, knowledge and quantitative tools available for various types of indoor environments. In general,

the assessment and comparison of results from different studies is complicated by large differences in their design, including duration, number of houses investigated, instrumentation used, and thus the measured parameters including particle size ranges. Among other gaps in knowledge, there have been relatively few studies reporting particle number concentration and the scatter of the reported results for size-classified particles is substantial. There is a need to explain and quantify the role of different mechanisms contributing to particle concentration levels and size distribution characteristics in mechanically ventilated large buildings. While there is some data available on indoor source emission factors, the data is still very limited and the variation in emission factors between the same types of sources is substantial; thus predictions through modeling of the level of increase in individual indoor environments is not very reliable. There are a number of existing mathematical models, however, discussion continues about improvements in terms of better model validation, accuracy, input requirements, and also a need for the development of new simulation tools capable of progressing with the new advances in the multi-disciplinary and complex field of indoor environments.

Nevertheless, despite these deficiencies a clearer picture of indoor particles, their concentration levels, trends in the concentrations and the factors affecting them, is emerging. In particular, there is a good understanding of the effect of the outdoor particle characteristics on those encountered indoors for naturally ventilated buildings, and on the relative contributions from the most significant indoor sources to the indoor particle concentrations. There is an understanding that the short term impact of indoor sources, particularly combustion sources is even stronger on particle number, than on particle mass, and the resulting concentrations can increase by a few orders of magnitude. There is also an increasing understanding on the production of particles through chemical reactions involving vapors and gases, through processes such as reactions between ozone and various terpenes in indoor environments, which have been shown to result in a significant increase in the number and mass concentrations of submicrometer particles.

The presentation reviews the state of knowledge regarding the abovementioned and other key aspects of indoor aerosols and outlines the needs and likely future directions of research and applications in this field.

Reinventing the Wheel: New Vistas for Aerosol Measurement
Richard C. Flagan

The core aerosol measurement methods, inertial separation, condensational particle detection, and electrical mobility measurements all have their roots in the 19th century, but only entered common usage in the mid to late 20th century. Electronic detection of light scattering enabled further advances: instruments that provided real-time assessments of aerosol concentrations and particle size distributions. The resulting flood of data from these instruments revolutionized aerosol science. Where early investigators examined so-called large ions and Aitken particles in broad classes, the electrical mobility analyzer revealed the multimodal nature of the atmospheric aerosol. Refined cascade impactors displayed the size dependence of the aerosol composition, and with that advance, provided insights into the physical and chemical mechanisms of aerosol particle formation and growth.

Manufacturers of aerosol instruments made the improved measurement methods available to the aerosol community at large; no longer were advanced measurement methods limited to those researchers who possessed the resources and skills to build their own.

Standardization reduced differences between measurements, and enabled the atmospheric aerosol to be characterized with rigor that had not previously been possible. Just as the nature of the atmospheric aerosol was revealed, the ideal aerosol measurement was defined, but remained unattainable even while aerosol theory advanced to the limits of available aerosol measurements and beyond.

The dawn of the 21st century brought a new era of invention in aerosol measurement. New generations of instruments expand-

ed routine aerosol measurements into the nanometer size regime, improved resolution of particle size and of the transient nature of the atmospheric aerosol. Near-real-time aerosol chemistry measurements, including determination of the chemical composition of individual aerosol particles, provide new insights into the nature of atmospheric particles; advances in laboratory-based analytical chemistry enhanced specificity in chemical species identification.

Combined with advances in statistical data analysis, trajectory modeling, and related simulation methods, these have enhanced the links between sources and the atmospheric aerosol. Long duration measurements of ultra fine atmospheric particle size distributions that have been enabled by computer-controlled instrumentation have shown that homogeneous nucleation in the atmosphere is not a rare event that can occur only in remote, and very clean environments; instead it has been seen virtually everywhere people have looked for it.

Still, major challenges remain. Aerosol measurements remain the purview of specialists. Instruments are expensive and required detailed knowledge to operate. While research-level instrumentation has undergone successive revolutionary developments, routine monitoring of the atmospheric aerosol has remained constrained by legal mandates. First PM₁₀, and, more recently, PM_{2.5} measurements have become the norm. Sampling networks have provided datasets that facilitated epidemiological studies of the health consequences of atmospheric aerosols, especially fine particles. Observations of aggravated respiratory problems in children who live near freeways where diesel trucks emit large numbers of particles in the low nanometer size range suggest that better data are needed. While legal definitions of air pollution problems are required by regulators, rigorous understanding of the health consequences requires much more. At the same time, epidemiological investigations demand measurements that can be widely deployed and continuously operated without fail; gaps in datasets due to instrument malfunction can seriously jeopardize efforts to unravel health consequences. To meet these needs, aerosol instrumentation must not only be made much more reliable than present laboratory tools, it must also be much less expensive to purchase and operate.

Occupational exposure measurements within the emerging nanotechnology industries face similar challenges. Mass measurements do not adequately assess potential threats of particles can translocate across cell membranes in the lungs to enter the circulatory system and other tissues, or into olfactory neurons through which they may migrate to the olfactory cortex. Differential mobility analyzers can characterize the aerosol, but cannot follow a worker to assess integral exposures.

New approaches that will enable these advances are on the horizon.

Radical approaches to aerosol measurement are being developed in laboratories around the world. A number of developments push the limits on resolution of aerosol particle size and chemical composition; aerosol mass spectrometry and condensation-enhanced particle sampling schemes are rapidly expanding our chemical understanding of the atmospheric aerosol. Others are addressing the challenges I have identified above. For example, new particle size analyzers may enable measurements of aerosol nanoparticles to be deployed into the extended networks required by epidemiologists. New sampling methods should facilitate improved chemical and biological characterization of atmospheric particles. By replacing operationally defined metrics, direct measurements promise to reduce the ambiguity in key atmospheric and exposure parameters. This presentation seeks to highlight a number of ongoing developments in aerosol measurement technology, to place those in context with the historical methods that have fostered the development of aerosol science to its present state, and to explore the evolving challenges to the aerosol measurement community.

Health Effects of Ambient Particulate Matter
Bert Brunekreef

The health effects of ambient particulate matter (PM) have been subjected to intense research in the last decades. Epidemiological studies have suggested that adverse effects on health occur both after short-term and long-term exposures. The lecture will provide an overview of epidemiologic research methods and findings.

Effects of short-term exposure have been investigated in time series studies, which take advantage of day-to-day or hour-to-hour variations in ambient PM concentrations caused by meteorological phenomena and/or temporal variations in sources e.g. rush hour traffic. The PM 'input' data in such studies are usually derived from routine monitoring stations. As a result, they are constrained to what is monitored (usually regulated metrics such as PM₁₀ or PM_{2.5}, particles smaller than 10 or 2.5 μm), and to where it is monitored (often urban background sites). The health 'output' data are also often derived from routinely collecting registries such as death registries or hospital admissions registries. Sometimes, studies are performed among specially selected subjects such as panels of asthma patients, or patients suffering from cardiovascular disease. As the use of data that have been collected already requires relatively few resources, hundreds of time series studies have been published. The collective evidence suggests that effects on mortality and hospital admissions occur at low levels of exposure, i.e. below current air quality guidelines and standards. Much attention has been paid to potential biases such as confounding by weather variables, gaseous air pollution components, and preferential publication of positive findings. Another issue that has been scrutinized is the extent of 'mortality displacement', i.e. assessment of by how many days or months death is being advanced by exposure to short-term increases in PM pollution. Other biases such as those related to measurement error and to the use of single days to characterize exposure have received less attention.

Effects of long-term exposure have been investigated in a small number of cohort studies. In cohort studies, carefully characterized groups of subjects living in areas with differences in PM exposure are being followed for periods of years to decades. The PM 'input' data again are usually routinely collected data, although there are a few examples of studies with dedicated PM monitoring. The health 'output' data consist of survival of cohort members or development of clinical or sub clinical disease. Because cohort members are carefully characterized with respect to potential confounding variables such as smoking, diet, occupation etc., cohort studies offer unique opportunities to single out PM effects. To date, only two or three cohort studies exist in the world that have been specifically designed to study long term effects of air pollution including PM. Other studies were started for different reasons, but have been taken advantage of by adding exposure assessment to ambient PM to it. The main cohort studies published to date suggest that effects on mortality and disease development occur at PM levels below current guidelines and standards, and that the loss of life expectancy associated with PM exposure may be substantial. In view of this, the data from two major U.S. cohort studies (the Harvard Six Cities Study and the American Cancer Society II study) have been extensively re-analyzed by a team of inde-

pendent researchers. This reanalysis has generally supported the original findings, but has also found that effects seem to occur primarily in subjects with only high school education or less. Also, the reanalysis suggested that PM effects were not easily distinguishable from effects of some of the gaseous components in ambient air. European cohort studies have focused on within-city contrasts in traffic-related air pollution mixtures, and have shown associations between these mixtures (characterized by nitrogen oxides or soot measurements) and survival.

Epidemiology is a largely observational science, for the obvious reason that experiments on humans can only be performed to a very limited extent. The causality of associations observed in epidemiological studies therefore needs to be addressed carefully. Elements contributing to a causal interpretation include repetition of findings under various circumstances, explanation of differences in findings by plausible differences in exposure to 'effect modifiers', plausible exclusion of alternative explanations by confounding variables or selection, and support from experimental studies in animals. In view of the complexity of ambient

PM it has been difficult to recreate ambient PM exposures in the laboratory. The use of particle concentrators has provided researchers with a unique tool to study PM effects in the laboratory without artifacts generated by PM collection and re-suspension. Evidence is now emerging from long term PM concentrator studies that support findings from epidemiology.

The results from the PM cohort studies have now been used in worldwide and European health impact assessment exercises, which in turn have been subjected to cost benefit analyses in support of PM policy development. Both in the U.S. and Europe, PM regulations are being updated in 2006. Also, the World Health Organization is preparing Air Quality Guidelines for worldwide application for the first time. At the conference, a brief overview will be given of the most recent decisions and proposals.

Primary Versus Secondary and Biogenic Versus Anthropogenic Organic Aerosol: Grand Challenges in Atmospheric Aerosol Research

Urs Baltensperger

Organic aerosol is either emitted as primary aerosol or formed in the atmosphere as secondary aerosol from gaseous precursors. In both cases, biogenic as well as anthropogenic sources contribute to the overall aerosol loading. Recent developments have substantially improved our understanding in this respect. As an example, carbon-14 analysis is able to distinguish fossil from biogenic carbon. Combined with a discrimination of the water soluble and water insoluble fractions this method offers a great potential in tackling the above challenges. Concerning secondary organic aerosol, the polymerization (or rather oligomerization) processes recently found in simulation chamber experiments have triggered extensive research all over the world. As a result of this oligomerization, larger molecules with a lower vapor pressure are formed. This results in higher yields of secondary organic aerosol, with different chemical and physical features. This in turn may induce substantial changes in the health and climate impact of the atmospheric aerosol. New and innovative interdisciplinary research has a great potential in further improving our knowledge in this exciting field of research.

Biography: Urs Baltensperger is currently head of the Laboratory of Atmospheric Chemistry, Paul Scherrer Institut in Switzerland and a lecturer at ETH Zurich. He studied chemistry at the University of Zurich. Since his doctoral thesis, he has been interested in aerosol research, focusing on physical and chemical aerosol characterization, heterogeneous chemistry, and aerosol effects on climate. He is chairman of the Scientific Advisory Group for Aerosol of the Global Atmosphere Watch program of the World Meteorological Organization (WMO), and president of the Commission for Atmospheric Chemistry and Physics of the Swiss Academy of Natural Sciences. He received the Professor Dr. Vilho Vaisala Award of WMO in 2003. He is author or co-author of more than 130 peer-reviewed papers, and has supervised about 20 doctoral theses.

Specialty Symposia at the International Aerosol Conference

In addition to several high quality technical sessions, tutorials and plenary lectures, there will be a series of specialty symposia.

Nanoparticle Related Symposia

A series of four symposia will be held in addition to the various technical sessions discussing various aspects of nanoparticle science and technology.

- Noninvasive Scattering Techniques for Nanoaerosol Characterization: Neutrons, X-Rays, and Light

Organizers: Barbara Wyslouzil and Chris Sorensen

Scattering of waves, be they electromagnetic, as light or x-rays, or neutrons, is the primary means by which science has determined the microscopic structure of matter. In aerosol science light scattering has been the primary scattering method used to detect and measure the morphology of the constituent particles. As science and technology delve into the nanometer regime, light scattering becomes insufficient for useful detection and measurement of nanometer sized particles. Thus new radiation sources and concomitant experimental technologies must be developed if wave scattering probes are to continue to be of great benefit to aerosol studies as they have been in the past. New sources and technologies appropriate for nanoscale aerosol scattering studies are currently being developed. These include synchrotron light sources in the x-ray and VUV wavelength ranges (0.2 to 200nm) and high flux neutron sources. These represent a new and growing technologies leading to ground breaking experimental methods. This symposium will bring together scientists who are either using these new devices or have interest to do so in order to: 1) exchange ideas and thus advance the field and 2) inform and educate other scientists, especially young scientists, of the opportunities, facilities and methods available in this burgeoning area.

- **Nanoparticle Dosimetry, Toxicology and Cellular Interactions** (Jointly with ISAM)

Organizers: Chong S. Kim, Wolfgang Kreyling and Marianne Geiser

The overall goal of this symposium is to address the importance of emerging nanoparticle technology, particularly related to effects on health. With hundreds of tons of nanomaterials already being made worldwide, potential impact of exposure to these tiny materials on health is enormous and yet is largely unknown. To highlight the impending issues the symposium will be organized with three sessions: 1) transport and deposition of nanoparticles in the respiratory tract (nanoparticle dosimetry), 2) cellular interactions with nanoparticles and 3) biological responses and toxicological effects. Both in vivo and in vitro experiments, mathematical models and computer simulation studies will be put together such that the symposium may serve as a forum for a broad aspect of nanoparticles in health. The symposium is sponsored jointly with International Society for Aerosols in Medicine and international experts in the featured topics will be invited as a lead speaker.

- **Nanomaterials and Occupational Health**

Organizers: Mark D. Hoover, Andrew Maynard, and Chuen-Jinn Tsai

The purpose of this symposium is to highlight research gaps, recent advances, and ongoing occupational health activities in aerosol science and technology related to the toxicity, health effects, exposure assessment, measurement, control, surveillance, risk assessment, risk management, and application of nanomaterials and nanotechnologies. Particular emphasis will be on accomplishments and opportunities for members of the International Aerosol Research Assembly to contribute to the methods validation, information sharing, and partnering aspects of aerosol science and technology for safe nanotechnologies. The format will include invited speakers and poster topics, submitted platform and poster presentations, and discussion sessions. Case studies describing workplace experiences and practices and measured particle characteristics are especially encouraged.

- **Industry Forum on Nanoparticle Science and Technology**

Organizers: Sheldon Davis and Pratim Biswas

The goal of this symposium is to have a forum to discuss industry needs in nanoparticle science and technology, and how aerosol scientists can contribute to the progress. The forum will include presentations by representatives from various industrial sectors – such as catalysis, powder production, chemicals

production, microelectronics and others. Presentations will provide a holistic view of the field as seen by industrial researchers. It is planned to organize a panel discussion to promote discussion and encourage audience participation.

Computer Software for Aerosol Research and Education

Organizers: Chang-Yu Wu and Kikuo Okuyama

Computer software is an important tool that provides researchers unforeseen insights into the aerosol system and helps them understand the dynamic behavior of aerosols. It offers possibilities of being used as an educational tool that can help students visualize complex aerosol systems and/or learn how to operate instrument in a virtual environment. Advances in information technology in recent years have greatly diversified the use of computer software in aerosol research and education. The goal of this symposium is to provide a mechanism that catalyzes the development and dissemination of such efforts. The symposium will be run in three formats with presentations via platform sessions, poster sessions and actual demonstration via computer stations. Topics of interest include various types of software and assessment methodologies, such as (but not limited to): aerosol mechanics; virtual instruments; data inversion; aerosol dynamics; simulation methods; visualization; aerosol chemistry; lab preparation; health/environmental risk assessment, and others. In addition, the plan is to discuss funding opportunities and publication mechanisms in the symposium.

Aerosol and Bioterrorism Defense

Organizers: Sergey Grinshpun and Ed Steubing

The goal of this symposium is to include a series of presentations related to the issues of homeland security and bioterrorism defense. Aerosol science and engineering can make signifi-

cant contributions in the detection of bioagents, and develop technologies for remediation. A series of presentations will discuss novel, real-time methods for detection of bioagents, their characterization and devices for capture and inactivation.
